ABSTRACT

Background: Condyloma acuminatum (CA) or genital warts is sexually transmitted infection resulting from Human papillomavirus (HPV). It is estimated that CA occurs in >80% of reproductive age in many countries, with the most common types being low risk types HPV 6 and 11, but sometimes could be combined with high-risk types are HPV 16, 18. Gen E6 is an oncoprotein that cooperates with E7 to provide a suitable environment for viral DNA replication and inhibits cellular apoptotic processes. The E6 gene has characteristic properties as a p53 tumor suppressor protein. Purpose: To analyse the high-risk types HPV 16 and 18 in CA patients. Methods: This study was a cross-sectional, observational analytic study that assessed data collection concurrently over time. Specimens were patients diagnosed with condyloma acuminatum, biopsies were performed, and immunohistochemical (IHC) staining was also performed to examine E6 of high risk types HPV 16 and 18. The sampling technique used sequential sampling, and the inclusion criteria included patients who came to our hospital for treatment. Result: Twenty patients with CA were include in this study consist of 11 male and 9 female, meanwhile 9 subjects in homosexual group and 11 subjects in heterosexual group. Based on IHC examination 33% cases were detected of high-risk types HPV 16 and 18 especially among homosexual group. According to t-test obtained significant result of high-risk types and low-risk types of HPV from IHC staining (p=0.038). Conclusion: Condyloma acuminatum is a sexually transmitted infection that commonly caused by low-risk types HPV 6 and 11, but this study showed high risk types HPV16 and 18 also found in MSM (Male Sex with Male) patients with CA, so that it is necessary to be aware of the possibility of transformation to malignancy.

Keywords: Condyloma acuminata, MSM, high risk HPV, Immunohistochemistry, Sexual Transmitted Infection.

BACKGROUND

Genital warts or condyloma acuminatum (CA) is sexually transmitted infections (STIs) caused by human papillomavirus (HPV), specifically subtypes 6 and 11, and are characterized by fibroepithelial neoplastic lesions on the skin and mucous membranes.1 The prevalence of HPV has increased rapidly over the past 3 years.2 CA has been found in adults of reproductive age. In general, HPV infection is very common, not only in patients between the ages of 20 and 40, but also in children and adolescents. There was no difference in the incidence of HPV by gender.3,4 It is estimated that CA infections occur in >80% of working-age men and women in many countries.5 Condyloma acuminatum is the most common STI, in Dr. Moewardi General Hospital, Surakarta, Indonesia.6 HPV mainly affects the epithelial cells of the skin and mucous membranes. Infection rates vary depending on the amount, type, intensity, and duration of viral particle exposure and the patient's immune status.4 Malignancy is a hazard caused by high-risk (HR) HPV.7 Some studies suggest that HPV infection is carcinogenic. The fact that interconnected processes, chronic inflammation, and important cofactors can provide new insights for approaches in pathogenesis.
and therapeutic. The purpose of this study was to identify HR-HPV in various condyloma acuminata.

**METHODS**

This study is an analytical, cross-sectional, observational study with data from July 2020 to October 2020 at Dr. Moewardi General Hospital, Surakarta, Indonesia. The study specimens were CA skin biopsy specimens that underwent both excision and core biopsy after a histopathological diagnosis of CA. In addition, one immunohistochemical staining for polyclonal HPV 16 and HPV 18 E6 Bioss antibodies® was performed at Pathology Laboratory Darma Usada November 2nd 2020 until November 14th 2020. Label and bind directly to the target antigen, a one-step staining method because there is only one labeled antibody. Histopathological diagnosis of CA and analysis of IHC staining was performed by a pathologist The interpretation was positive if cells were stained in the nucleus or combined in the nucleus and cytoplasm. Categorical variables were described as numbers and percentages and continuous variables were expressed as medians. The demographics characteristic data include sex, age, occupation, sex orientation, and HIV status. The difference in the expression of gen E 6 HPV 16 and 18 on CA patients with low risk strain HPV and high risk strain HPV groups infection was analyzed by t-test. All data were statistically analyzed with SPSS version 22 and a p-value of 0.05 was considered significant. This study was approved by the Health Research Ethical Committee of Dr. Moewardi Hospital/Faculty of Medicine, of Sebelas Maret University, Surakarta, Indonesia (803/VI/HREC/2020).

**RESULT**

Our sample consisted of 20 patients, 11 male and 9 female, aged 16 to 67 years, mean age was 41.27 ± 14 years, based on sexual orientation are grouped into 2 categories, namely homosexual (40 %) and heterosexual (60%). In contrast, all women with CA had heterosexual Table 1 described the demographic data from all the subject of the study who were patient diagnosed with CA from July to October 2020 at Dr. Moewardi General Hospital. In this table, most patients were younger than 50 years (90%). Patients were mainly students and private employees, depending on their occupation, 14 (70%). Only 1 patient is official. According to anti-HIV testing, 6 male CA patients with HIV positive (66.7%) and all females revealed HIV negative. When examining HPV strains, 3 patients are MSM (33.3%) showed HR HPV strains. HR-HPV was not found in women (Table 2).

HIV=Human Immunodeficiency Virus
The HPV genome is divided into three main parts, namely, long control region (LCR), early region (E) and late region (L). The E region codes for proteins required for viral gene expression, replication and survival. E6 is an oncoprotein that cooperates with E7 to provide a suitable environment for viral DNA replication and inhibits cellular apoptotic processes. The E6 gene has characteristic properties as a p53 tumor suppressor protein. Stained slides were analyzed by two pathologists for variable representation of epithelial and stromal components and immunoreactivity. Squamous epithelial cells, with brown-colored cytoplasmic staining for E6,7 protein, were identified and graded as follows: 0, no staining; 1.1–25% staining; 22.6–50% staining; 3.51–75% staining; and 4.76–100% staining. The staining intensity for each marker was not taken into consideration. The examination and scoring of immunohistochemistry slides were confirmed by a panel of more than two certified professionals in pathology. The results revealed gen E6 positivity in 3 cases of 20 patients (15%).

DISCUSSION

Condyloma acuminata commonly associated with HPV 16 and 18 subtypes infections with most contagious and tend oncogenic behavior. Those types lead epidermal dysplasia and develop to malignancy. Based on genotyping study reported 70% cases of squamous cell carcinoma on the cervix related to carcinoma of the vulva, penis, vagina and oropharynx. Condyloma acuminata can be established by history taking and physical examinations, meanwhile immunostaining and polymerase chain reaction (PCR) testing can be used to demonstrate oncogenic potency. Figliulo et al. reported the incidence of HPV infections among HIV-infected male mostly observed in heterosexual group. In a study of Zambian patients, 56.8% of males were said to have had unprotected sex eventhough after genital ulcers. In Brazil, Figliuolo et al. HPV incidence has been observed in HIV-positive heterosexual men. The prevalence of HPV infections in our study commonly found in heterosexual compare to homosexual group (60% : 40%). Previous study from Insinga et al. reported that CA mostly occurs among women over the age of 20 and men over 25-years-old, in contrast to our result that the highest incidence of CA among women over 31-years-old. One of Karadaghy et al. A cross-sectional study conducted found that 5.5% of students contracted CA during the study period.
The transmission rate of condyloma acuminata between infected and susceptible partners is high, about 65%. The incubation period of HPV infection was 3 weeks up to 8 months, and the median time to appearance of skin lesions was 2 months. Our study revealed 6 male patients (30%) with HIV reactive, 5 of them were homosexual. Patients with untreated HIV infection more easily to get CA due to immune system imbalance against the virus. Several studies showed the correlation between CA and HIV/AIDS incidence mostly in homosexual sexual group. A study in Africa reported a significant association between HPV infection and HIV, with immunocompromised patients more likely to develop dysplastic lesions and potential HPV reactivation. Because HPV is considered more contagious than HIV, given the impact of HPV infection on HIV transmission, it is possible that women were exposed to both infections and were infected with HPV before HIV, assuming the effect of HPV infection on HIV transmission. In our study, 3 patients were found to have The HR-HPV strain (15%) was found only in gay men, and one of the 16-year-olds had a child if any previous sexual intercourse was denied. Sexual abuse was found to have a 37% chance of CA. 4-8 year olds, 70% of children over 8 years old. A meta-analysis study reported that HR-HPV was more common among HIV-positive MSM and bisexual men than HIV negative men. A study of male volunteers in Kenya found that 3.8% of men with HR had an increased risk of HIV seroconversion-HPV. High-risk HPV integration, particularly types 16 and 18, was associated with cervical large cell neuroendocrine carcinoma. A retrospective study revealed which men had a higher HPV-associated contingency of developing KA, intraepithelial squamous anal lesions and HPV-associated anal carcinoma, compared with women. Whereas men and women share the main HPV types, prevalence varies between the man and women. There are differences in prevalence between sexes. In men, most high-risk carcinogenic types are associated with HPV 18. In women, HPV 16 is the most common high-risk type. Individuals who are immunosuppressed are said to have higher rates of HPV infection, are resistant to treatment of HPV-related diseases and are also prone to accelerated progression of HPV-associated cancers. Concluding that condyloma acuminata is a common sexually transmitted disease often associated with HIV infection. Several types of HPV are highly infectious and oncogenic potency particularly in MSM, whereas immunostaining analysis can be used to determine the high risk oncogenic strains. All patients with HR-HPV in our study are MSM. Furtherly, examination of high risk strains of CA using IHC staining can be done with a larger and varied number of samples, and can also be used as a screening in cases of suspected malignancy.

Limitation Of The Study
A Single centre study with small sample.
