ABSTRACT

Infection of Staphylococcus epidermidis is still a common problem in many hospitals. Factor determining biofilm formation makes it harder for antibiotics to cure the infection. Roselle (Hibiscus sabdariffa), a well known traditional medicine plant, is a potential candidate as a drug against infectious disease. The purpose of this research is to investigate the antibacterial effect of ethanol extract from Roselle (Hibiscus sabdariffa) calyx against the growth of Staphylococcus epidermidis. Assessment for antibacterial effect is performed using broth diffusion method. The extract is made by maceration of the calyx of Roselle in 96% ethanol. Extracts with concentration of 125, 62.5, 31.25, 15.63, 7.81, 3.90, 1.95, 0.97, 0.48, 0.24 mg/mL are added into separated Mueller-Hinton broths (MHB), which have already been inoculated by Staphylococcus epidermidis. As for bacterial growth control, we used MHB with bacterial inoculation, while sterility control we used mixture of extract and MHB. Then from each broth, the solutions are added into separated nutrition agar plates. Replications are done three times. Clarity and bacterial growth are observed after 24 hours of incubation. However, clarity cannot be observed in 36 broth, but bacterial growth is observed on the plate for concentration 0.97, 0.48, and 0.24 mg/mL. Therefore Minimum inhibitory concentration (MIC) cannot be determined because the extract’s color interfere the observation. While minimum bactericidal concentration (MBC), the last concentration before the concentration where the bacteria are still viable, is 1.95 mg/mL. Based on the result of the research, the Roselle calyx ethanol extract (Hibiscus sabdariffa) through dilution method with a concentration of 1.95 mg / mL can kill Staphylococcus epidermidis and in order to find MIC in colored and turbid solution (before being incubated in incubator), we can consider using agar dilution method or microdilution method.

Keywords: Hibiscus sabdariffa, antibacterial, Staphylococcus epidermidis, biofilm, flavonoids

ABSTRAK

Infeksi Staphylococcus epidermidis masih merupakan masalah umum yang ditemukan di banyak rumah sakit. Kemampuan bakteri untuk membuat biofilm mempersulit atibiotik untuk menyembuhkan infeksi. Rosella (Hibiscus sabdariffa), tanaman obat tradisional yang umum beredar di masyarakat, adalah bahan yang berpotensial untuk dikembangkan menjadi obat untuk mengatasi infeksi. Tujuan dari penelitian ini adalah untuk mengetahui efek antibakteri dari ekstrak etanol kelopak Rosella (Hibiscus sabdariffa) terhadap pertumbuhan Staphylococcus epidermidis. Penelitian ini merupakan penelitian eksperimental laboratorik dengan metode dilusi. Ekstrak Rosella dibuat dengan cara maserasi dari tampuk Rosella dengan menggunakan etanol 96%. Kemudian dilakukan pengenceran sebanyak 10 kali didalam 10 tabung. Konsentrasi yang didapatkan adalah 125, 62.5, 31.25, 15.63, 7.81, 3.90, 1.95, 0.97, 0.48, 0.24 mg/mL. Masing-masing tabung sudah berisi bakteri. Sebagai kontrol tumbuh bakteri digunakan campuran bakteri dengan Mueller-Hinton broth dan kontrol sterilitas menggunakan cairan ekstrak dengan Mueller-Hinton broth. Kemudian dari ke-12 tabung, dilakukan streaking pada media nutrient agar plate untuk melihat pertumbuhan dari bakteri. Replikasi percobaan dilakukan sebanyak 3 kali hasil percobaan diamati setelah inkubasi selama 24 jam. Hasil penelitian yang didapat, dari 36 tabung tidak dapat diamati kejernihan dari tabung. Hal ini disebabkan warna dari ekstrak mengganggu dari kejernihan pengamatan sehingga tidak dapat ditentukan nilai dari konsentrasi hambat minimal (KHM). Kemudian dari nutrient agar plate, didapatkan pertumbuhan bakteri pada
With the increase in *Staphylococcus* resistance and Roselle medical potential, we need further research regarding the antibacterial effect of this plant. In this study, researcher aims to investigate the antibacterial effect of Roselle extract on the growth of *Staphylococcus epidermidis* in vitro.

### MATERIAL AND METHOD

#### Plant Material Extraction

The flowers of *Hibiscus sabdariffa* were purchased from UPT Materia Medica in Batu small town, east java. The plant materials were taxonomically identified by a botanist at the same location. Calyces of the plant were separated and ground to a fine powder. About 250 g dried powder was taken and soaked with 96% ethanol. The wet powder is put in a jar and as much as 1500 mL 96% ethanol was poured into the jar. The jar was then closed tightly for 24 hours and placed on the shaker with 50 rpm. After that the suspension was filtered and was placed into erlenmeyer. The sediment from the filtration was re-maceration with the same technique (1500 mL 96% ethanol). The ethanolic extract was evaporated with rotary evaporator for 2 hours and water bath for 1 hour. The final result from the extraction was 77 mL extract with concentration 250 g/mL.

#### Antibacterial Assay

Prior to the experiment, a colony of *S. epidermidis* was subcultured in Mueller Hinton Agar (MHA) and incubated for 24 hours at 37 °C. The bacteria were then adjusted by adding normal saline to be equivalent to 0.5 McFarland standard which comprised 1.0 x 10^8.

#### Susceptibility Testing Procedure

The experiment was repeated 3x. The extract was dispensed in 1 mL volume in each sterile tube with decreasing concentration starting from 125 g/mL. Each tube was then inoculated by 1 mL volume of diluted *S. epidermidis*. The growth control tube consists of 1 mL inoculum and extract free medium while the sterility control contains 1 ml extract and 1 ml medium. All tubes were incubated at 37 °C and MICs were read after 24 hours of incubation.
RESULT

A total of 30 tubes were tested for MIC. The result of the MIC is shown in Table 1.

Overall, by using macrodilution method the MIC couldn’t be determined. This result happens because the extract’s red color and turbidity interfere with the observation and the assessment. The same condition could also be seen in sterility control tube because of that it couldn’t be used as a comparison to determine sterility, so in order to determine the extract’s efficacy, each of the 30 tubes was streaked into nutrient agar plate to determine MBC value which was shown in Table 2.

From the experiment, it can be determined that the MBC of Roselle extract against *S. epidermidis* is 1.95 mg/mL (1.56%).

DISCUSSION

Roselle is a great plant to be used for medical purpose. First, it is easily grown in tropical country like in Indonesia and has many properties. The time required to grow is around 4 to 8 months with the lowest temperature 20°C, 13 hours lighting, and 130 to 250 mm of rainfall for each month.9 With these condition, people can easily get the plant and cultivate it. Second, it is known to have many good effects. Roselle has antimicrobial, anti-parasite, anti-cancer, anti-pyretic, anti-inflammation, anti-oxidant, nephro-protective, hepato-protective, diuretic, anti-cholesterol, antidiabetic, and antihypertensive.6, 10-11

From the result, the MIC in the experiment couldn’t be indentified because of the extract’s red colour and turbidity. To find out the result of the MIC, extract Roselle can be tested with another dilution method. In Nigeria, research was conducted by Mary12. She did MIC testing by agar dilution method. She examined the antimicrobial effect of Roselle against *Staphylococcus aureus*, *Bacillus stearothermophilus*, *Micrococcus luteus*, *Serratia marcescens*, *Clostridium sporogenes*, *Escherichia coli*, *Klebsiella pneumoniae*, *Bacillus cereus*, and *Pseudomonas fluorescence* with MIC 0.30 ± 0.2-1.30 ± 0.2 mg/mL. A similar research was conducted by Sulistyani13 and her research group with microdilution method. They tested antimicrobial activity against mouth pathological bacteria that could make biofilm. These bacteria were *Streptococcus mutans*, *Streptococcus sanguinis*, *Lactobacillus casei*, *Actinomyces naeslundii*, *Aggregatibacter actinomycetemcomitans*, *Fusobacterium nucleatum*, *Porphyromonas gingivalis* and *Prevotella intermedia* with MIC and MBC 7.2 mg/mL to 28.8 mg/mL and 14.4 to >57.6 mg/mL. Interestingly, Roselle extract also has the ability to inhibit biofilm formation on the concentration of the MIC.13 The formation of biofilm is also found in *S. epidermidis*.4

The overall mechanism how Roselle extract has antibacterial effects is still not completely comprehended. In USA, Marjorie, Janak, Jacqueline, Shurrita, and Leonardo were conducted a research about the antimicrobial activity of *Hibiscus sabdariffa* against *E. coli*. By using disk diffusion method, they concluded gain conclusion that all concentration (10%, 5%, and 2.5%) of *H. sabdariffa* could

inhibit *E. coli* activity in from food, veterinary, and clinical samples and showed that the most effective concentration was at 10%, whereas the least effective concentration was at 2.5%. They were stated that the antimicrobial effect of *H. sabdariffa* might come from its flavonoids chemical. The structure of flavonoids have the ability to form combined complex with bacterial walls. Besides that, the number of hydroxyl groups present on the phenolic ring helps the antimicrobial activity of the extract. Due to the increase of hydroxyl group, the hydroxylation would accelerate and cause the increase of antimicrobial activity.\(^7\) Issam and Ahmed also were stated a similar discussion that phenolic compounds including flavonoids and cyaniding contribute to antimicrobial activity. They added that flavonoid with its phenolic chain could decreases iron level and increases hydrogen level, which deactivates bacterial enzymes.\(^{14}\) Moreover Sulistiyani et al. reported that Flavonoids are also thought to have the ability to inhibit the formation of bacterial biofilms. This capability is possible because the phenolic group in the extract capable to bind strongly to proteins and enzymes from the bacteria. This makes the bacteria unable to produce biofilms.\(^7\) This effect is important considering *S. epidermidis* and some gram-positive and gram-negative bacteria capable of producing biofilms.

Based on the research that has been conducted, Roselle calyx extract can be used as a alternative treatment for infections caused by *Staphylococcus epidermidis*.

**CONCLUSION**

The Roselle calyx ethanol extract (*Hibiscus sabdariffa*) through dilution method with a concentration of 1.95 mg/mL can kill *Staphylococcus epidermidis* and in order to find MIC in coloured and turbid solution (before being incubated in incubator), we can consider using agar dilution method or microdilution methode.
