ABSTRACT

Overproduction of numerous pro-inflammatory cytokines, during dengue virus (DENV) infection, has been related to plasma leakage in the vascular endothelium and studied elsewhere with conflicting results. The current study objective is to evaluate the expression of four cytokine/chemokine genes following DENV-2 infection within peripheral blood mononuclear cells (PBMC) isolated from a healthy donor. Venous blood was drawn, and PBMCs were isolated using Ficoll density gradient centrifugation. Cells were maintained in culture medium and infected with Indonesian isolate of DENV-2. Cells were harvested and followed by total RNA extraction and reverse-transcription into cDNA using oligo d(T) primers and Reverse Transcriptase enzyme system. The SYBR Green-based quantitative qRT-PCR was used to calculate the relative expression of IL-6, IL-8, IP-10 and MIP-1β encoding genes during infection time points, compared to uninfected cell controls. The observation of the cytokine was on the 6 and 18 hours post-infection. The different expression profiles of cytokines/chemokines were observed. The up-regulation of gene expression was observed for IL-8 and IP-10. In contrast, the down-regulatory of IL-6 and MIP-1β genes expression was documented during the infection period. The cytokine IL-8 and IP-10 are potent chemoattractants in the recruitment of neutrophil, basophil, and lymphocytes in response to an infection. The highlight of this study is on the up-regulation of IL-8 and IP-10 genes expression which may confirm the roles of these chemokines in the pathogenesis of dengue infection.

ABSTRAK

Produksi sitokin pro-inflamasi berlebihan pada infeksi virus dengue yang dihubungkan dengan terjadinya kebocoran plasma pada endotel vaskular telah diteliti dengan hasil yang bervariasi. Penelitian ini bertujuan untuk mendeteksi ekspresi empat gen pengkode sitokin atau kemokin pada sel mononuklear darah tepi yang di-infeksi virus dengue serotipe-2. Sel mononuklear darah tepi (PBMC) diisolasi dari donor sehat dengan menggunakan metode sentrifugasi gradient Ficoll. Ekstraksi RNA dilakukan terhadap sel mononuklear darah tepi, kemudian sintesis cDNA dilakukan dengan menggunakan primer oligo d(T) dan sistem enzim reverse transcriptase. Dengan menggunakan quantitative Real-Time Polymerase Chain Reaction (qRT-PCR) berbasis SYBR-Green, ekspresi gen penyandi IL-6, IL-8, IL-10 dan MIP-1β dibandingkan antara sel yang terinfeksi dan tidak terinfeksi virus dengue serotipe-2. Observasi dilakukan pada waktu pengamatan jam ke-6 dan waktu pengamatan ke-18 dari infeksi. Ekspresi gen penyandi IL-6 dan IL-10 ditemukan lebih tinggi, sebaliknya ekspresi gen penyandi sitokin IL-8 dan MIP-1β lebih rendah pada sel mononuklear darah tepi yang diinfeksi virus dengue serotipe-2 dibandingkan dengan kontrol Interleukin-8 dan IP-10 adalah sitokin yang bersifat sebagai kemotaktik untuk memicu kemotaksis dari sel netrofil, basophil dan limfosit sebagai respons dari suatu inflamasi. Hasil penelitian ini menunjukkan bahwa ekspresi kedua gen penyandi kemokin yang meningkat setelah infeksi virus dengue serotipe-2 mungkin berperan pada patogenesis terjadinya kebocoran plasma pada infeksi virus dengue.

INTRODUCTION

Infection caused by dengue virus is still the major cause of acute febrile illness in the world, particularly in the tropical and subtropical area, including Southeast Asian countries. The widely-spread dengue virus (DENV) and the Aedes mosquitoes vector have now become a major problem, and more than 125 countries are known to be dengue-endemic regions, including Indonesia. The high DENV expansion is related to climate change, globalization effect, traveling communities, socioeconomics, settlement and viral evolution. Dengue is a complex disease, caused by an RNA virus, entailing of four antigenically similar but with immunologically distinct serotypes (DENV-1 to DENV-4). A serotype-specific DENV infection confers life-long immunity with only partial protective immunity for the other serotypes hence people in endemic countries can be infected up to four times by different DENVs. The clinical manifestation varies from asymptomatic to the severe, life-threatening manifestation. The majority of dengue clinical manifestation is mild, asymptomatic dengue or mild fever. In the lesser incidence, the more severe form of dengue is Dengue Hemorrhagic Fever (DHF) with various degrees and Dengue Shock Syndrome (DSS), in which the fatality rate may exceed more than 5% in special populations. Expanded dengue syndrome or unusual dengue syndrome with a high mortality rate can be appeared without any sign of plasma leakage, the hallmark of severe dengue.

The detailed pathogenesis of dengue is not yet entirely understood. The existence of cytokine storm-induced endothelial dysfunction in DENV infection has been published over the past decades. The excessive release of various cytokines recognized as cytokine storm has been regarded as the underlying mechanism of plasma leakage in DENV infection. The role of diverse cytokines and chemokines were observed during the more severe manifestation of dengue might be considered to be correlated with the infecting DENV serotype. At the different phase of illness, cytokines/chemokines profiles were found to be increased in patients at the febrile phase. Several studies were also reported the increased expression of cytokines/chemokines within in vitro in human monocytes or epithelial cells or in vivo in dengue patients’ serum. The dual role of both innate and inflammatory pathways were activated during dengue disease and revealed the involvement of immune mediators. Utilizing dengue human cell line infection model, the up-regulated cytokines/chemokines gene expression profiles during DENV serotype infection have been described and among them were IL-6, IL-8, and IP-10. Other report is highlights the induction of MIP-1β by dengue virus. In this study, we are reported the expression profiles of four genes encoding cytokines and chemokines in the peripheral blood mononuclear cells (PBMCs), infected with Indonesian isolate of DENV-2.

MATERIAL AND METHOD

Ethical Considerations

The ethical considerations of this study have been reviewed and approved by the Institutional Review Board of Udayana University, Bali, Indonesia (Document No. 2072/UN.14.2/KEP/2017).

Blood Collection and Peripheral Blood Mononuclear Cells (PBMCs) Isolation

Thirty mL of venous blood was drawn from a healthy donor and subjected to PBMC isolation using Ficoll Histopaque-1077 (Sigma-Aldrich, St. Louis, MO) density gradient centrifugation. Isolated PBMCs were maintained in 1 RPMI medium supplemented with 10% of fetal bovine serum (FBS), 1% of antibiotic/antimycotic, and 2 mM of L-glutamine (all from Gibco-Thermo Fisher Scientific, Carlsbad, CA). Cells were seeded at 1 10⁶ cells per well of 24-well plates (Corning, NY). The seeded cells were allowed to rest during overnight incubation at 37°C incubator with 5% CO₂ supplementation.

DENV Infection

The DENV-2 virus strain SMG-SE001 was isolated from a severe dengue patient from Semarang in 2012 (Eijkman’s collection). Cells were infected with DENV-2 using the multiplicity of infection (MOI) of 1 (theoretical calculation of one virus PFU per cell), prepared in 1 RPMI medium-2% FBS, performed in duplicate. To achieve the MOI of 1 (theoretically one virus particle infecting one cell), a number of 10⁶ Plaque Forming Unit (PFU) of DENV-2 was inoculated into 10⁶ PBMC cells. The DENV PFU titre was measured using a standard plaque assay method, as described elsewhere, meanwhile uninfected cells controls were inoculated using the addition of medium only. Plates were then incubated for 1 hour at 37°C, 5% CO₂ to facilitate virus infection. The incubation period was continued and cells were harvested at 0, 6, and 18 hours post-infection to represent the early phase of dengue illness.

Total RNA Extraction and qRT-PCR

Infected cells were harvested at the designated time points and subjected to the total RNA extraction using miRCURY RNA Isolation kit – Cell and Plant (Exiqon, Vedbaek, Denmark), as described in the manufacturer’s instructions. Total RNA quantity was measured using Qubit 3.0 fluorometer and Qubit RNA BR Assay Kit (Life Technologies-Thermo Fisher Scientific, Eugene, OR). An amount of 100 ng of total RNA was used in cDNA synthesis performed using oligo (T) primer and GoScript Reverse Transcription System (Promega, Madison, WI). The resulting cDNA was then amplified by quantitative real-time PCR using GoTaq qPCR Master Mix (Promega) and primers as listed in Table 1. The relative gene expression analysis was performed using the equation of 2^−ΔΔCt of normalized Ct value to human β-actin.
RESULT AND DISCUSSION

The increased expression of IL-8 and IP-10 was observed during infection of DENV-2, with the highest level seen at 18 hours post-infection (Figure 1). By contrast, the relative expression of IL-6 and MIP-1β genes was relatively decreased along the infection time. The up-regulation of IL-8 and IP-10 was reaching more than two-fold at 18 hours post-infection, relative to the uninfected by macrophages and other cell types, such as endothelial cells, fibroblasts, and synovial cells.17 It has been reported that increased levels of IL-8 cytokine in the sera of dengue patients were correlated with the severe form of dengue.18 The level of IL-8 was significantly higher in samples from severe dengue cases and lower in cases of dengue without warning signs than in healthy controls. Samples that were positive for anti-DV IgG antibody had higher levels of IL-8.18

The IP-10 is a member of CC-motif chemokine in response to interferon-γ in infectious diseases.18 The previous study result on the induced expression of IP-10 chemokine has been well-documented in dendritic cells and other primary cell lineages in response to in vitro dengue infection19 as well as in PBMCs of dengue patients.20 The level of IP-10 has been found to be increased in serum of dengue-infected patients in studies in Venezuela19 and Singapore.21 Moreover, the increased level of IL-8 and IP-10 cytokines/chemokine was also observed in A549 human lung epithelial cells infected with DENV.13

We observed the reduction trend in both IL-6 and MIP-1β gene expressions during DENV-2 infection of PBMCs. The increased level of IL-6 has been reported in dengue patients.22 In addition, the increased level of IL-6 has been correlated to disease severity with higher level observed in the more severe form of dengue manifestation, through the up-regulation of inflammatory responses in macrophages and induction of B cell maturation.23 Dengue NS1 protein was found to significantly increase the production of IL-6 thoroughly activation of TLR-2 and TLR-6 in PBMC infected with DENV.24 The higher expression of MIP-1β was reported in PBMC from DENV-infected patients.11 However, in this study we did not found the elevated level of gene expressions for IL-6 and MIP-1β within 18 hours of DENV infection. A systematic review on markers of dengue disease severity revealed that increased level of IL-6 and MIP-1β was observed in samples taken more than

control. The reduction of IL-6 and MIP-1β genes expression to the level of nearly half-fold was apparent at the same time points.

We observed the up-regulation of IL-8 and IP-10 in PBMCs infected with DENV-2, relative to the uninfected controls. The IL-8 is the pro-inflammatory cytokines, a member of CXCL chemokine family and the factor of a neutrophil chemotactic factor, which have been widely investigated and found to increase at the protein level.17 The cytokine IL-8 is a neutrophil chemoattractant produced

48 hours after onset of fever. The results from this study may be related to the difference in the experimental setup of genes expressions analysis and the designated sample collection period to represent the early phase of dengue disease development during 18 hours of virus infection. However, the decreasing levels of IL-6 and MIP-1β have been observed in dengue with warning signs during disease progression from febrile to convalescence phase.11 The current study result concordant to another study result where increased serum levels of IL-6 and IL-8 were detected in patients with dengue haemorrhagic fever but not dengue fever.26 More in-depth research is needed to study the kinetics of these cytokines during dengue infection.

CONCLUSION
It has been reported here the dynamic of four cytokines related to an early phase of DENV infection. The up-regulation of IL-8 and IP-10, chemokines with profiles that highly correlated with dengue than other febrile diseases and have the potential to be used as a biomarker of dengue, since high expression of these cytokines at the earlier phase of observation in this study.

ACKNOWLEDGEMENT
This work was supported by the Faculty of Medicine and Health Science, University of Warmadewa. We would like to thank Prof. Aryati, Prof. Yoes Prijatna Dachlan, Dr. Sunaryo, Dr. H. Muchlis A. Udji, and Dr. Gondo Mastutik, for their critical inputs and suggestions to the study.
