SYSTEMATIC REVIEW

Stress exposure due to the COVID-19 pandemic on menstrual abnormalities: A systematic review

ABSTRACT

Objective: COVID-19 pandemic has caused a considerable increase in stress levels due to reduced human mobility, interaction, and activity. High stress levels are often associated with adverse health outcomes. Stress influences female reproductive systems, where it is an important indicator of female health. This systematic review aims to analyze the relationship between stress levels due to the COVID-19 pandemic and the incidence of abnormal menstruation.

Materials and Methods: This systematic review was registered in PROSPERO international database (CRD42023433296). Literature were conducted across four databases, Pubmed, Web of Science, Science Direct, and Google Scholar, with boolean AND and OR operators as keyword search assistants. Literature was searched and limited to journals published during the pandemic (2019-2023), written in English, an open access article, and meet the keyword. Literature whom not a research study, duplicated and limited access were not included. Inclusion journal will be screened by PRISMA flowchart and EPHPP Assessment Tool for Quantitative Studies for the quality assessment.

Results: Nine out of 1150 journals were eligible for review. Seven studies revealed that there was a significant relationship between stress and anxiety due to the COVID-19 pandemic and the incidence of menstrual abnormalities. However, one study revealed that these changes were not significant.

Conclusion: There is a significant relationship between stress during the COVID-19 pandemic and the incidence of menstrual abnormalities.

Keywords:
Menstrual abnormalities
Stress
COVID-19 pandemic
Maternal Health

Highlights:

1. There is a significant higher level of stress during COVID-19 pandemic.
2. The highest menstrual abnormalities during pandemic cases were found in premenstrual syndrome and dysmenorrhea, and the lowest was found in menstrual cycle disorders (polygomenorrhea, oligomenorrhea, amenorrhoea).
INTRODUCTION

Menstrual cycle is one of vital sign on women's health. Women under 30 continue to experience problems related to hormones and menstruation, especially abnormal menstruation. Abnormal menstruation not only causes discomfort for women and interferes with women's quality of life, it also associated with poor health outcomes, such as an increased risk of coronary heart disease, type 2 diabetes mellitus, and cardiometabolic diseases. On the other hands, menstrual cycle has become one of women indicator of overall women health, although sometimes it were overlooked by several health practitioners. Abnormal menstruation that commonly occurs is dysmenorrhea, premenstrual symptoms, menorrhagia, polymenorrhea, abnormal vaginal bleeding, amenorrhea, oligomenorrhea, and irregular menstruation.

High levels of stress are often associated with adverse health outcomes. Stress can cause or exacerbate significant health problems, including cardiovascular disease, obesity, sexual dysfunction, digestive problems, and mental health conditions. Stress also influences female reproduction, where stress involves the hormonal system as a system that plays a significant role. Several studies were found a relation between stress and menstrual abnormalities.

COVID-19 pandemic has caused a relatively high increase in stress levels due to reduced mobility, interaction, and human activity. This situation tend to be stressful for some individuals. During COVID-19 pandemic, prevalence rate of stress in general population was found to be higher, especially on women and younger age groups. High levels of anxiety and stress have led to the emergence of other studies regarding the relationship between the pandemic and abnormal menstruation or disruption of the menstrual cycle. The prevalence of population experienced severe dysmenorrhea during the pandemic were higher than before pandemic occurred. Based on this background, there need a further exploration regarding the relationship between exposure to stress due to the COVID-19 pandemic and the incidence of abnormal menstruation.

MATERIALS AND METHODS

This systematic review was registered in PROSPERO international database (CRD42023433296). The research begins by determining research questions, PICO, quality assessment, data extraction, and reporting.

Menstrual abnormalities during the pandemic

Menorrhagia

The incidence of menorrhagia during a pandemic was found in four study. Medina-Perucha et al. found 7.2% of their respondents experiencing an increase in bleeding. In line with study by Samo et al. which found that 15% of the respondents experienced heavy bleeding during the COVID-19 pandemic. In line with the research of Phelan et al. who also mentioned that 28% of the respondents had menstruation for more than eight days. Higher result found on study by Maher et al. which stated that 50% of their respondents felt that their menstrual volume during the pandemic had also increased.

Hypomenorrhea

Hypomenorrhea also found during the COVID-19 pandemic. The incidence of hypomenorrhea was found in four study. Takmaz et al. found that 2.5% of their respondents experienced reduced blood volume during menstruation. In line with the study by Maher et al. which 5.1% of their respondents experienced a reduction in menstrual days, and 5% experienced a reduction in menstrual volume. Samo et al. also revealed a decrease in menstrual volume in 16.75% of their respondents. Phelan et al. on their studies also revealed that 29% of their respondents experienced menstruation in under two days.

Amenorrhea

Cases of secondary amenorrhea during the pandemic were also found in three studies. Medina-Perucha et al. found that 2.5% of their respondents experienced amenorrhea due to pregnancy, intrauterine disorders, and implants.

</table>
revealed that their respondents did not get menstruation for at least one cycle during the pandemic. In line with the study of Phelan et al.\textsuperscript{11} which found their respondents did not experience their periods during the pandemic. Research conducted by Samo et al. also found that 16% of the respondents experienced amenorrhea during the pandemic.\textsuperscript{12,13} Higher percentage were found on studies of Garcia de Leon et al.\textsuperscript{14}, which found that 23.7% of their respondents, specifically 13.1% of their under 40s respondent having fewer periods than before

**Dysmenorrhea**

Dysmenorrhea is one of the most common findings during a pandemic. Six studies were found talking about dysmenorrhea. Medina-Perucha et al.\textsuperscript{15} revealed an increase in menstrual pain out 12.6% of the respondents. Studies conducted by Aolymat et al.\textsuperscript{16} also found that during the pandemic, there was an increase in severe dysmenorrhea by 13% compared to before the pandemic. Payne et al.\textsuperscript{17} also revealed that the increase in stress and distress due to COVID has a relationship with more significant menstrual pain disorders. Samo et al.\textsuperscript{14} also found that respondents to their study experienced dysmenorrhea. Higher percentage were found in these three latest study, Garcia de Leon et al.\textsuperscript{18} found that 44.3% of their respondents indicated more symptomatic on their periods, specifically 52.7% of their under 40s respondent. Phelan et al.\textsuperscript{11} found that 49% of their respondents experienced higher dysmenorrhea than before the pandemic and Maher et al.\textsuperscript{14} were also revealed that 59% of their research respondents experienced dysmenorrhea during the pandemic.

**Premenstrual Syndrome**

Cases of premenstrual syndrome were also found in some of these studies. Phelan et al.\textsuperscript{11} revealed that 53% of respondents experienced premenstrual syndrome worse than before the pandemic. Payne et al.\textsuperscript{17} also revealed that increased stress and distress due to COVID are related to more frequent and severe menstrual symptoms. In other research, Maher et al.\textsuperscript{14} revealed that 68% of respondents experienced more severe premenstrual syndrome symptoms than before the pandemic. In line with the study conducted by Aolymat et al.\textsuperscript{16} which also found an increase in the frequency of premenstrual syndrome

**Oligoamenorrhea**

Oligoamenorrhea or shortened menstrual cycles have been found in four studies during COVID-19 pandemic. Samo et al.\textsuperscript{14} revealed that 3% of the respondents in this study experienced a decrease in the length of the menstrual cycle. In other study, Medina-Perucha et al.\textsuperscript{15} stated that 10% of respondents experienced shorter menstrual cycles. Higher results found on Garcia de Leon et al.\textsuperscript{14} studies which stated that 15.7% of their respondents, specifically 19% of their under 40s respondent having shorter periods than before. However, research conducted by Phelan et al.\textsuperscript{11} and Nguyen et al.\textsuperscript{14} showed no significant changes in the average cycle and duration of menstruation.

**Oligomenorrhea**

Oligomenorrhea have also been found in five studies. Samo et al.\textsuperscript{14} revealed that 7.2% of their respondents experienced a cycle extension. Takmaz et al.\textsuperscript{10} found that 12.9% of female medical personnel experienced lengthening and menstrual cycle lengthening during the pandemic. In other research, Maher et al.\textsuperscript{14} also revealed that 12.5% of their respondents experienced longer menstrual cycles. Garcia de Leon et al.\textsuperscript{15} were also found that 25.4% of their respondents, specifically 32.1% of their under 40s respondent indicated longer periods than before. However, less significant changes in mean cycle and menstrual length were found by Takmaz et al.\textsuperscript{10} and Maher et al.\textsuperscript{14}, which remained at 28 days, but there was wider variability in minimum and maximum cycle length.

**Menstrual abnormalities on COVID-19 pandemic**

The difference in results related to abnormal menstruation can be attributed to the stress level experienced by the respondents. Eight of nine journals in this systematic review stated that higher levels of depression, anxiety, and stress were associated with menstrual abnormalities. Phelan et al.\textsuperscript{11} stated that respondents with low mood, anxiety, and/or stress had a higher prevalence of changes in their menstrual cycle, worsening premenstrual symptoms, dysmenorrhea, and reduced libido. Garcia de Leon et al.\textsuperscript{15} also stated that their analysis show there were twice as many respondents who indicated changes in symptoms due to the Pandemic control measures. In line with the research by Payne et al.\textsuperscript{17}, stress during the pandemic is associated with an increase in menstrual pain, the number and severity of premenstrual syndrome, and menstrual pain disorders. These menstrual abnormalities can also disturb a woman's quality of life.\textsuperscript{18}

Broke down of the supply chains in the world, shutdown of retail stores, and mandated restrictions of movement during COVID-19 lockdowns has giving negative affect of menstruators physical and mental health.\textsuperscript{20,21} The stress response is based on the hypothalamus-pituitary-
adrenal (HPA) axis. Exposure to physical, social, and environmental stressors causes the secretion of various hormones and dysregulation of HPA axis activity.\(^2\) The HPA axis is activated during stress, which results in CRH secretion from the hypothalamus. CRH acts on the pituitary, facilitating the release of adrenocorticotropic hormone (ACTH), which interacts with the adrenal cortex and stimulates the release of cortisol. Chronic stress will produce an irregular HPA axis, as shown by glucocorticoids inhibiting the action of gonadotropin-releasing neurons (GnRH), gonadotrophs, and gonads. Excessive CRH levels can also cause inhibition of the hypothalamic-pituitary-gonadal (HPG) axis. Other obstacles that can occur include decreased pituitary response to GnRH, resulting in decreased secretion of luteinizing hormone (LH), giving a direct inhibitory effects of glucocorticoids on sex hormone secretion, glucocorticoid-induced resistance to gonadal steroids in target tissues, and direct catecholaminergic inhibition of FSH, LH secretion, and prolactin.\(^2\)

Contrasting to the stress levels, study conducted by Nguyen et al.\(^2\) states that the absence of this relationship may be related to the sociodemographics of the respondents. This study was conducted on women with a college education in their 30s and in relationships. These criteria have been considered in several studies to be able to adapt well during the COVID-19 pandemic. This statement is supported by research by Kwak et al.\(^2\) and Andiarna\(^2\) which states that abnormal menstruation is commonly found in women with lower socioeconomic status and education. Significantly, seven out of eight studies concluded that there was a link between stress during the pandemic and abnormal menstruation. The highest cases were found in premenstrual syndrome and dysmenorrhea, and the lowest was found in menstrual cycle disorders (polyomenorrhea, oligomenorrhea, amenorrhea).

Limitations of this study were found on choice of language, difference in the use of questionnaires in each study which some studies do not include the results of their validity, and the lack of sources, which limited to open access study. This limitations reduces the diversity of information which can be included in this systematic review.

**CONCLUSION**

There is a significant relationship between stress during the COVID-19 pandemic and the incidence of menstrual abnormalities. Future researchers are expected to be able to study further the effect of stress during the COVID-19 pandemic on menstrual disorders. They deepen into reasons of menstrual cycle-related disorders have less prevalence than other disorders and the relationship between stress levels
